# Distributed Energy Storage Smart Cost

## Overview

---

How much does a distributed generation system cost?

Furthermore, the optimal solutions from integrating distributed generation units such as WFs, PVFs, and BESS also bring great benefits compared to the non-integrated system. In the base system, total costs are very high and equal to \$44.5685 million. On the contrary, the total costs are significantly smaller in the modified system.

How does a distributed power system work?

As plotted in Fig. 9, during hours with favorable natural conditions (strong wind and high solar radiation), the distributed sources supply high power to the grid and almost enough to supply the entire demand of the system.

Why is Bess a good energy charging/discharging strategy?

Besides, BESS, with a reasonable energy charging/discharging strategy according to each electricity price period, also greatly saves operating costs. It can also be affirmed that determining the appropriate operating strategy for units is necessary to maximize the received benefits.

What if a distributed generation unit does not have enough power?

Realistically, if distributed generation units (WFs, PVFs, and BESS) do not have enough power to supply the loads due to high demand and low generation, purchasing electrical energy from the traditional power plants through the substation at the slack node is necessary.

How much energy does a Bess system store?

As a typical example, in this system, BESS's rated energy is 1.9871 MWh with a rated charging and discharging power of 0.8049 MW. In other words, BESS can store up to 1.7884 MWh, which is considered full energy, and the remaining energy of 0.3974 MWh is considered exhausted energy.

What is the energy storage process of Bess?

In addition, to further elucidate the operation of BESS, Fig. 19 also shows the energy storage process of BESS throughout 24 h of a day. As a typical example, in this system, BESS's rated energy is 1.9871 MWh with a rated charging and discharging power of 0.8049 MW.
